

Masking reviled

The clues from Jim:

"The masking technique may not be [a known technique]... That's part of the puzzle I told [Jim] I would keep secret." - Excerpt from interview in Wired Magazine.

"I used a bit of stego when designing the fourth part of Kryptos." - Excerpt from cryptography discussion.

Standing waves are the result of two sinusoidal waves of the same frequency in a common medium traveling in opposite directions. The displacement of each wave has a combined affect that produces the superposition of a stationary wave.

It may be easier to visualize three separate waves. The first wave (above) appears to be traveling in a horizontal direction while the second wave is traveling in the opposite direction. The two waves do not collide; rather the amplitude of each at any given moment is combined into the effect of a single amplitude resulting in the standing wave. If the troughs and crests of the traveling waves range in maximum displacement of -1 to +1 unit, the troughs and crests of the standing wave will have a maximum displacement of -2 to +2 units.

From the outside of the cylinder, all text would be legible and the only viewpoint rendering backward text would be from the center of the cylinder, and you would have to be in a pool of standing waves.

Not only does superposition occur in the pool of water; it occurs in K3 of the copperplate (the third passage which is located in the bottom half of the cipher text side). The position of three of the characters are superscript or super-positioned. In fact, those characters are Y, A, and R consecutively.

spatial systems of encoding and decoding

******* End of Clues**

This is the key clue on how to find the mask.

The mask is reviled by turning the text on its side. If you use a 1 for a letter is present and a zero for no letter present, you get 28 four bit nibbles of binary data. This is the mask control.

In 4 bit nibbles it is: E033337333137337313337131713

The clue to extract the mask is from the Morse T is your position. The first letter out of place is the T, so I started extraction from there.

The other part that is raised is also binary, the D^{YA}H^R This is 0 "1101" This is the other part, I will call the mask.

Now how to apply the mask is the next part. So we have two parts a control that tells us whether to apply the mask or not, and the mask itself. The mask control can be binary 1=yes apply mask, 0=no do not apply mask.

Then how to apply the mask, it can be XOR with the alphabet then modulo26 added to the cipher, cipher can be xor with the mask and added modulo26 added. It can indicate to use alphabet 0 or alphabet 2 Many ways. It can be nibbles that are shift values.

Then we have 2 alphabets One being the one with the L since its out of spatial context.

GHIJLMNQUVWXZKRYPTOSABCDEF GHIJ L ←---
KRYPTOSABCDEF GHIJLMNQUVWXZ

This can then be a alberti cypher with two wheels keeping with the idea of clocks. Then the mask can be to use alphabet 0 or 1 to decode.

Many possibilities to still go thought yet.

But I feel confident with the mask, and the mask control extraction.

So the way to solve is much easier now as we have a way to unmask the data.

On the encryption I don't think it's the same technique. He would use something different here keeping with the visual clues. So I like the rings, but another clue is there to tell us what it is.

So that's it for now what do you think.
