

HYDRAvsDYAHRvsWIDIAvsDIAWIvsDWAI

Paul Kiesel
11/22/2023

Coupla things.

1. I remember when that member first mentioned the word **HEADER** that shows vertically in K3 CT. I didn't find anything when I first looked at it, mostly because of the word's orientation and nothing obvious nearby that would indicate a rotation or something. When he brought it up the second time, I looked again and didn't see anything again, but he mentioned that the H was the same H between YA and R in **DYAHR**. That made me look harder and I found that the **HEADER** string does describe the left fold in Sanborn's note sheet number 3. Funny how one's mind can settle on an idea and not see the obvious.

2. I responded to the recent posting about **DYAHR**. The reason I did this was to show the group the relationship between **DIAWI** and **DYAHR** via the obvious relationship with **HYDRA**. I showed the relationships as:

HYDRA = 12345 - **DYAHR** 32514
WIDIA = 12345 - **DIAWI** 32514.

As I proofread my response, I noticed also that:

DIAWI = 12345 - **DWAI** 14325 (14325 is **KRYPTOS** without Y=7 and T=6, the two letters adjacent to the center letter, P).

DWAI is the "nuance" version of **DIAWI** that shows up in positions 31 to 35 in the 16 shift version of K4 (+Z) CT. Now, I already recognized that the nuance versions of **DIAWI**, **INFBN** and **NSKGS** all had the positions of their second and fourth letters reversed. But, this second method of generating the nuance versions is new to me. This means that the **NUANCE OF IQLUSION** is related to **DYAHR** and, ultimately, **HYDRA**!! Am I stretching the limits of association? Maybe.

This definitely deserves a deeper look.

Before going too deeply into this, we take note of the seemingly related facts that:

1. The nuance versions of **DIAWI**, **INFBN** and **NSKGS** all have the letters adjacent to the middle letter reversed, generating **DWAI**, **IBFNN** and **NGKSS** as the nuanced versions.

2. The relationship of **DIAWI** = 12345 with **DWAI** = 14325 shows that the nuance version **DWAI** has the order 14325, which is the same order as **KRYPTOS** = 1473625, but with the numbers adjacent to the middle number, 3, missing.

This combination of facts implies that there is a relationship involving the two letters adjacent to the center letter of subject strings.

Several things to check in chasing this down occur to me. The most obvious are to try changing the keyword KRYPTOS to:

1. KRPOS
2. KRTPYOS

and modifying the tableau to have those options replace KRYPTOS as the alphabet keyword, then run known matrices using those modified tableaux.

I tried running the above strings as alphabet keys using K4 CT as ciphertext (because JS has been pushing lately that the solution has 97 letters). I came across nothing that really stood out, though I have to admit that there were more options to try. But...

I came to the conclusion that the probability exists that the relationships described regarding the strings I mentioned on page 1 lead the solver to recognize the form arrived at (DWAI) by modifying the DIAWI that appears after the word KLU in K4 CT, the conclusion being that the position occupied by DWAI in the 16-shift version of K4 CT and its modified appearance with the double letters at the end, points to the similarly constructed NGKSS that lies in that same position in K4 CT. Analysis involving the three strings mentioned on page 1 shows that all three of the strings, whether in original form or in modified form, occupy only the same three positions in the texts, regardless of the caesar shifts involved. The version of NGKSS that appears in K4 CT amounts to the NUANCED version of the original version which appears in the 10-shift version of K4 in the same position as DIAWI does in the zero-shift version. This 10-shift version is the one we use in moving forward in K4 after we insert the Z in front.

So, the DWAI form is another clue to get to the 10-shift version of K4. In my work, I used the fact that DIAWI, besides being in the original form of K4, also exists in the same form in the 21-shift version. After studying the three strings found in two versions of the shifted text, I looked harder and found DWAI, which lead to finding IBFNN and NGKSS. I finally deduced that the version of NSKGS I needed was the one where NSKGS appears in the same positions as DIAWI does in the zero-shift version of K4.

So, there are two ways at least leading to the 10-shift version of K4. Kryptos has numerous instances of multiple clues to reach conclusions about things.

That is the long way of explaining my conclusion re DIAWI and DWAI via WIDIA and DYHR.
