

Requesting verification of key extraction method

Note: I am rewriting this to make it clearer,
My apologies, adding crack tips

I would like verification of this as a viable method to extract keys from morse up to the point up to k4, giving us an odd unknown.

The method. Visual clues.

The extraction key is kryptos. Literally carved out. The method is one time pad.

This assumes no knowledge of the method, is not a solution, and runs on the basis of an op in the field with cryptographic knowledge to extract a key.

This is a summary.

Step 1. Decode morse. That becomes the one time pad. We are only concerned with

whats "Inbetween" words ex: shadow
forces "adowf" (side note, as vig, and otp
ally invi works with k1, invi alone will reveal
small bits of keys in both)

Step 2. Recreate the enciphered grid. Put
in a monospaced font. Like courier. Look
at the bottom for the example. Typewriter
text.

Step 3. Extract the clue xueen. How do we
find this? In the grid below.

At the top next to xueen, in k2. You
will see the word "CLUE" written right
before the X in xueen. Vertically.

Step 4. Adowf in morse as pad + xueen in
cipher = lescha, which is plaintext of k1.

step 5. Use lescha to get 5 characters of the
key:

skim fill crib method:

(rumkin, viginere, kryptos keyword, lesa as cipherkey, decrypt, start deleting the chars at the beginning of k1, watch the solution at the bottom, you will see a limp start repeating) place those points in a sanborn style chart then convert the other areas of text to plain. you'll gain a lot of plain text, now you can fill in the blanks, then reverse with assembled plaintext, assemble the key. Do this with other sections. a one time pad version can be replicated as well and you can see it all at once. That would be another story.

All three 5 character segments of each other will flip and give each other as a result.

Step 6. Crib drag the now solved k1 as a pad vs k2, you will find one of those 3 keys pop up. Proves a "Rotation" They flip each other.

Step 7a. **k3 decrypt without keys (rotation)**

Just as the clue keep rotating in one direction.

This could be done on grid paper but use rumkin rotate and ctrl+x, ctrl+v

Three options are **14x24, 7x48 and 8x42**

**you can easily find these by removing carriage returns and resizing a text window. start with ciphertext, set the columns to one of the above, (width of

table) go to the solution area, “cut” it, paste it into the source area, change the columns to something different, repeat.

The text will roll. alternate between two, even if you forget to alternate once, keep rolling, once you get used to it you can do the whole kryptos text, 30x29.

Occasionally you can see plaintext pop up vertically diagonally skipped etc.

Eventually it will rotate back around to cipher. I think you can cycle a text in under 20 movements. I was told this isnt a known crack.**

Step 7b. Continuation of clue extraction isn't dependent on known ciphertext at this point for k3. But a trap was put in.

Step 8. The puzzle is literally split in two on copper plates. We have the top half solved if the clues were followed.. If not we keep

otp dragging as the path was made. We now focus on the bottom half. Place k4 AS A PAD against k3. I think k4 is not the ciphertext but the pad. Or elements. This doesn't stop extraction. (you can use k4 as a pad and as cipher, as cipher it starts with vovjjjjj as pad you get tutddddd, tutddddd makes a pretty alignment on a tableau, eoibi in k4 lines up vertically and even spaced under the d column. i will reply with a picture.

Step 9. We fail. We hit the trap. If we start at the beginning of k3 and use it vs k4, there is a keyword offset. We start skimming and give up. I did. Until I realized the trap.

Step 10. The trap is k4 or part of it is a pad. Or treated like one. (Yes i've segmentally inverted it no luck) Go

to rumkin cipher page, use k4 as a pad.
Plop k3 as ciphertext. Go to the beginning
and hit delete over and over on k3.
The solution changes. Use this to drag.
You will hit tutddddd which is eye catching.
Flips with CPTEOIBI as k3 ciphertext.

step 10a. The trap. If you look at sanborns
decoding charts you see he likes to have
the plaintext, the key, then ciphertext
written out on a grid. Normally starting
with k3 and skimming will throw you. He
restarts with kryptos at CPTEOIBI which
reveals itself as tutddddd or vovjjjjj which
is a 1 in 580000 chance per refs.

Backtracking you would have yptoskr. He
skipped two letters to throw off the trail. I
will paste the results at the bottom.

Monospace it. Courier

Leftovers

1. "nceof" is repeated twice up top and he includes it with his clue pointer between subt "lesha" ding and the abse "nceof" light lie the nua "nceof" of iqlusion
2. I haven't found a rotator for this yet.
3. in the grid below you will notice dyahr surrounding a Q.
4. (Top Matrix) Originally we saw a poor quality version of this document. a 14 x 24 grid. It had end.. written on it. I thought that was the "End" but maybe not. Could be the end in k3 restarting... or the rotation.. but....
5. In the new version. We have a number 15 at the very bottom and xue in one square. xue is part of another side of a puzzle. A matrix. Like they mate somehow.
6. pcpcpc..... there is a "-->/" with the / under the "x can you see.." text. Unknown reason. You can only see this in the raw

nova video with premiere pro. 1 frame.

7. K4 has a definite pattern if you put it in a 14 x 7 matrix and rotate it once counterclockwise. The implications, are that the plaintext may be written out, then rotated, then enciphered. meaning you would have to solve left to right bottom to top vertically aligned text. Not a native setup for cracking analysis or computers. you are cracking gibberish and then reading it vertically. A "mask"? Not sure. try it yourself.

8. google cryptoscope as an alternative rotate tool. be patient the page is very slow to load. old zodiac killer tool. you can flip and mirror text with it too.

-Floyd Yancey
