

Sanborn worksheets from 2010. Check marks under (J)K and Y

E O

L I

Y Q

^

Misspellings LOE --> QUA (E) are in

from left --> 11th column, 22nd column

from right 6th column, 3rd letter missing in despAratEly <--

11 22 63. Well known date. Build code key table from left to right 11 (missing E is col 15) 22 6 first three letters ASK (ask not what?), ends UU (UndergrUUund and end UU= WW?) Note next to last line KAIN, last line DTUU.

Face Kryptos screen w/ crypto text running left to right, then look at Vig, it is modified Beaufort (ELYOIE**CBA**QK). Set up decoding table as follows: top row (1) backwards ABC, second row (2) regular ABC. Then Beaufort KRYPTOS (3). Build the key K from the bottom up UU to 96 97, etc.¹

K	C	3	2	1
T	N	H	L	O
E	Y	J	J	Q
U	P	A	S	H
D	V	E	O	L
M	T	E	O	L
R	T	Y	X	C
T	M	G	M	N
T	Z	Q	F	U
O	F	S	T	G
I	P	G	M	N
E	K	H	L	O

As you can see, quite a few well known initials show up in this little matrix. JS and JAE are well known, of course. They are next to each other on the photo too! Is JK Jae Ko? She does some nice sculpture work herself. LOE are the letters replaced with QUA. LO, of course, ...

¹ To create OBKR and "paint" the cobra and mongoose, see photos, very flexible keys are needed for positions 1-48 and 86-97 (the tail in shape of a figure 3). This is obtainable consistently via the inherent flexibility in Quag coding and K4 final stage methodology. Between 49-86 the key is less flexible if it comes from K3, though as we have seen from EN DYHR OHN etc. some artistic flex

can be built in there as well. The body of the mongoose requires less design detail so the text and transposition algorithm tests can be run along with a C selection more focused on other things. Of course, in these scenarios we are just talking potential intermediate Cs, need to solve the masking, or initial, step to get at plaintext in these kinds of theories.

Fun stuff!/KR
