

The two characters highlighted in green below are the misspellings from K1 and K2.

The three characters highlighted in purple below are the raised characters in K3.

The two characters highlighted in yellow below are the misspellings from K3.

The raised characters and misspellings when rearranged spell "LAYER". Jim Sanborn specifically noted that the misspellings are important. He also stated that what was important was not necessarily the misspelled character that was important but rather the character's location.

Starting with the two misspelled characters from K1 and K2, scroll down their columns until you reach the characters located within the first row of K3, which are "ID"

If you combine the characters "ID" with the raised characters and misspellings located on the same row, and once we rearrange them, we now have "ID LAYER."

Now why is this significant?

Well, using those characters noted above from row one of K3 as column identifiers, I was able to mark columns from K1 and K2. There are 7 columns each containing 14 characters. That is a total of 98 characters, and one of those characters are a question mark. That leaves us with 97 characters and one "?" as seen below. I

believe I have identified the matrix needed to solve K4. Now what to do with it I am unsure at the moment.

5473612

YARLEID

1234567

IDLAYER

Perhaps 5473612 is the order in which to substitute k4 or add it. Then again it could be nothing.

I do not believe that in K2 "IDBYROWS" and "XLAYERTWO" was just a coincidence.

I believe it was a clue.

ID BY ROWS

X LAYER TWO

ID LAYER
